ABSTRACT

A wireless power system can include wireless power receive
circuitry for generating power from a wireless signal, and a
wireless power transceiver for communicating with a wire-
less power transmission unit. The wireless power system can
transition from an idle state to different power management
states depending on whether or not communication has been
established with the wireless power transmission unit. Dif-
ferent modules can be activated, different supply voltages,
and different clock signal rates can be used in different power
management states.

WIRELESS POWER SYSTEM**CROSS REFERENCE TO RELATED
PATENTS/PATENT APPLICATIONS**

The present U.S. Utility Patent Application claims priority pursuant to 35 U.S.C. §120 as a continuation of U.S. Utility application Ser. No. 14/257,149, entitled "BATTERY WITH INTEGRATED WIRELESS POWER RECEIVER AND/OR RFID", filed Apr. 21, 2014, which is a continuation of U.S. Utility application Ser. No. 13,766,995, entitled "BATTERY WITH INTEGRATED WIRELESS POWER RECEIVER AND/OR RFID", filed Feb. 14, 2013, issued as U.S. Pat. No. 8,716,977 on May 6, 2014, which is a continuation of U.S. Utility application Ser. No. 12/793,458, entitled "BATTERY WITH INTEGRATED WIRELESS POWER RECEIVER AND/OR RFID", filed Jun. 3, 2010, issued as U.S. Pat. No. 8,390,249 on Mar. 5, 2013, which claims priority pursuant to 35 U.S.C. §119(e) to U.S. Provisional Application No. 61/264,925, entitled "WIRELESS POWER SYSTEMS AND METHODS", filed Nov. 30, 2009, all of which are hereby incorporated herein by reference in their entireties and made part of the present U.S. Utility Patent Application for all purposes.

BACKGROUND OF THE INVENTION**1. Technical Field of the Invention**

This invention relates to power conversion and more particularly to wireless power conversion and supporting communications thereof.

2. Description of Related Art

The concept of wireless power (i.e., powering a device without an electrical power cord) has been around for a while and has recently been commercialized. In addition, there are a couple of on-going standards discussions (WPC—wireless communication alliance and CEA—consumer electronics association) to standardize wireless power systems.

Current commercially available wireless power products include a transmit unit, a receive unit, and a bidirectional control channel. In these products, the primary method of energy transfer is inductive coupling, but some lower power applications may include solar energy transfer, thermo-electronic energy transfer, and/or capacitive energy transfer. To use these products, the receive unit is a separate unit that must be coupled to a device that is to be wirelessly powered. Thus, the device itself cannot be wirelessly powered without the receive unit coupled to it.

To develop these products, effort has been spent on inductive power transfer, closed loop systems, and multiple load support. In the area of inductive power transfer, effort has been spent on optimizing the tuning the transmit and receive circuits (each of which includes a single inductor) for resonance, efficiency, and/or thermal issues, detecting loads, turning off the inductive power transfer, coil alignment, magnetic alignment, lower phantom power, Class D, E power transmitters with load compensation, antenna design, and coil switch-

2

ing. In the area of multiple load support, effort has been spent on power sharing and tuning, control channel multi-access, and collision avoidance.

In the area of closed loop systems, effort has been spent on regulating the transmit power, the transmit resonance, alignment to maximize safety and/or power transfer using a particular control channel protocol (e.g., backscatter, IrDA, or Bluetooth). As such, as long as the receive unit and transmit unit are from the same vendor using the same communication protocol for the control channel, wireless power transfer can occur. While the above referenced standards organization are attempting to establish standards regarding the control channel protocol, currently, vendors are free to use whatever protocol they chose, making compatibility issues between different vendors' wireless power products.

While effort has been spent to commercialize wireless power systems, there is still SIGNIFICANT effort needed to make cost-effective and/or feature rich wireless power systems.

BRIEF SUMMARY OF THE INVENTION

The present invention is directed to apparatus and methods of operation that are further described in the following Brief Description of the Drawings, the Detailed Description of the Invention, and the claims. Other features and advantages of the present invention will become apparent from the following detailed description of the invention made with reference to the accompanying drawings.

**BRIEF DESCRIPTION OF THE SEVERAL
VIEWS OF THE DRAWING(S)**

FIG. 1 is a schematic block diagram of an embodiment of a wireless power system in accordance with the present invention;

FIG. 2 is a schematic block diagram of another embodiment of a wireless power system in accordance with the present invention;

FIG. 3 is a schematic block diagram of another embodiment of a wireless power system in accordance with the present invention;

FIG. 7 is a schematic block diagram of an embodiment of a portion of a wireless power system in accordance with the present invention;

FIG. 8 is a schematic block diagram of another embodiment of a portion of a wireless power system in accordance with the present invention;

FIG. 9 is a schematic block diagram of another embodiment of a wireless power system in accordance with the present invention;

FIG. 10 is a schematic block diagram of another embodiment of a wirelessly powered device in accordance with the present invention;

FIG. 11 is an example state diagram of a processing module of a wirelessly powered device in accordance with the present invention;

FIG. 12 is a logic diagram of an embodiment of a method for a charge set up state in accordance with the present invention;

FIG. 13 is a logic diagram of another embodiment of a method for a charge set up state in accordance with the present invention;

FIG. 14 is a logic diagram of an embodiment of a method for a charge state in accordance with the present invention;

FIG. 15 is a diagram of an example of a graph of charge need versus charge efficiency in accordance with the present invention;

FIG. 16 is a logic diagram of an embodiment of a method for a wirelessly powered power management state in accordance with the present invention;

FIG. 17 is a logic diagram of an embodiment of a method for a battery powered power management state in accordance with the present invention;

FIG. 18 is a schematic block diagram of an embodiment of a wireless power computer system in accordance with the present invention;

FIG. 19 is a schematic block diagram of an embodiment of power modules within a wireless power computer system in accordance with the present invention;

FIG. 20 is a schematic block diagram of an embodiment of a computer power module in accordance with the present invention;

FIG. 21 is a schematic block diagram of another embodiment of a computer power module in accordance with the present invention;

FIG. 22 is a schematic block diagram of an embodiment of a peripheral device power module in accordance with the present invention;

FIG. 23 is a schematic block diagram of another embodiment of a peripheral device power module in accordance with the present invention;

FIG. 24 is a schematic block diagram of another embodiment of a wireless power system in accordance with the present invention;

FIG. 25 is a schematic block diagram of an embodiment of a wirelessly chargeable battery in accordance with the present invention;

FIG. 26 is a schematic block diagram of another embodiment of a wirelessly chargeable battery in accordance with the present invention;

FIG. 27 is a diagram of an embodiment of a wirelessly chargeable battery in accordance with the present invention; and

FIG. 28 is a diagram of another embodiment of a wirelessly chargeable battery in accordance with the present invention.

DETAILED DESCRIPTION OF THE INVENTION

FIG. 1 is a schematic block diagram of an embodiment of a wireless power system that includes a wireless power (WP) transmit (TX) unit 10 and one or more devices 12-14. The WP TX unit 10 includes a processing module 18, a WP transceiver 20, and a power TX circuit 16. Each device 12-14 includes a WP receive (RX) circuit 22, 28, a processing module 26, 32, and a WP transceiver 24, 30. The device 12-14 will most likely include a plurality of other components depending on its desired functionality. For example, the device 12-14 may be a cell phone, a personal audio/video player, a video game unit, a toy, etc. and includes the corresponding circuitry.

The processing modules 18, 26, 32 of the WP TX unit 10 and in each of the devices 12-14 may each be a single processing device or a plurality of processing devices. Such a processing device may be a microprocessor, micro-control-

ler, digital signal processor, microcomputer, central processing unit, field programmable gate array, programmable logic device, state machine, logic circuitry, analog circuitry, digital circuitry, and/or any device that manipulates signals (analog and/or digital) based on hard coding of the circuitry and/or operational instructions. The processing module 18, 26, 32 may have an associated memory and/or memory element, which may be a single memory device, a plurality of memory devices, and/or embedded circuitry of the processing module 18, 26, 32. Such a memory device may be a read-only memory, random access memory, volatile memory, non-volatile memory, static memory, dynamic memory, flash memory, cache memory, and/or any device that stores digital information. Note that if the processing module 18, 26, 32 includes more than one processing device, the processing devices may be centrally located (e.g., directly coupled together via a wired and/or wireless bus structure) or may be distributedly located (e.g., cloud computing via indirect coupling via a local area network and/or a wide area network). Further note that when the processing module 18, 26, 32 implements one or more of its functions via a state machine, analog circuitry, digital circuitry, and/or logic circuitry, the memory and/or memory element storing the corresponding operational instructions may be embedded within, or external to, the circuitry comprising the state machine, analog circuitry, digital circuitry, and/or logic circuitry. Still further note that, the memory element stores, and the processing module 18, 26, 32 executes, hard coded and/or operational instructions corresponding to at least some of the steps and/or functions illustrated in FIGS. 1-28.

The WP TX unit 10 communicates with the WP transceivers 24, 30 of the devices 12-14 via one or more control channels 34 that use one or more frequencies in the ISM bands 36 and/or one or more frequencies in another non-licensed frequency band(s) 38. The communication via the control channel 34 may use one or more standardized protocols 40, 44 and/or one or more proprietary protocols 42, 46. For example, the standardized protocols 40, 44 may include Bluetooth (2400 MHz), HIPERLAN (5800 MHz), IEEE 802.11 (2400 MHz and 5800 MHz), and IEEE 802.15.4 (personal area networks using 915 MHz or 2400 MHz).

The ISM bands 36 include:

Frequency range	Center frequency
6.765-6.795 MHz	6.780 MHz
13.553-13.567 MHz	13.560 MHz
26.957-27.283 MHz	27.120 MHz
40.66-40.70 MHz	40.68 MHz
433.05-434.79 MHz	433.92 MHz
902-928 MHz	915 MHz
2.400-2.500 GHz	2.450 GHz
5.725-5.875 GHz	5.800 GHz
24-24.25 GHz	24.125 GHz
61-61.5 GHz	61.25 GHz
122-123 GHz	122.5 GHz
244-246 GHz	245 GHz

Each of the WP power transceivers 20, 24, 30 (e.g., in the WP TX unit 10 and in each of the devices 12-14) includes baseband processing (which may be done by the corresponding processing module 18, 26, 32), a radio frequency (RF) and/or a millimeter wave (MMW) transmitter section, and an RF and/or MMW receiver section. In an example of operation, the baseband processing converts outbound data into outbound symbol stream in accordance with one or more wireless communication standards (e.g., GSM, CDMA, WCDMA, HSPA, HSDPA, WiMAX, EDGE, GPRS, IEEE

802.11, Bluetooth, ZigBee, universal mobile telecommunications system (UMTS), long term evolution (LTE), IEEE 802.16, evolution data optimized (EV-DO), proprietary protocol, etc.). Such a conversion includes one or more of: scrambling, puncturing, encoding, interleaving, constellation mapping, modulation, frequency spreading, frequency hopping, beamforming, space-time-block encoding, space-frequency-block encoding, frequency to time domain conversion, and/or digital baseband to intermediate frequency conversion.

The transmitter section converts the outbound symbol stream into an outbound RF signal that has a carrier frequency within a given frequency band (e.g., ISM bands 36). In an embodiment, this may be done by mixing the outbound symbol stream with a local oscillation to produce an up-converted signal. One or more power amplifiers and/or power amplifier drivers amplifies the up-converted signal, which may be RF bandpass filtered, to produce the outbound RF signal. In another embodiment, the transmitter section includes an oscillator that produces an oscillation. The outbound symbol stream provides phase information (e.g., $\pm\Delta\theta$ [phase shift] and/or $\theta(t)$ [phase modulation]) that adjusts the phase of the oscillation to produce a phase adjusted RF signal, which is transmitted as the outbound RF signal. In another embodiment, the outbound symbol stream includes amplitude information (e.g., $A(t)$ [amplitude modulation]), which is used to adjust the amplitude of the phase adjusted RF signal to produce the outbound RF signal.

In yet another embodiment, the transmitter section includes an oscillator that produces an oscillation. The outbound symbol provides frequency information (e.g., $\pm\Delta f$ [frequency shift] and/or $f(t)$ [frequency modulation]) that adjusts the frequency of the oscillation to produce a frequency adjusted RF signal, which is transmitted as the outbound RF signal. In another embodiment, the outbound symbol stream includes amplitude information, which is used to adjust the amplitude of the frequency adjusted RF signal to produce the outbound RF signal. In a further embodiment, the transmitter section includes an oscillator that produces an oscillation. The outbound symbol provides amplitude information (e.g., $\pm\Delta A$ [amplitude shift] and/or $A(t)$ [amplitude modulation]) that adjusts the amplitude of the oscillation to produce the outbound RF signal.

The receiver section receives and amplifies an inbound RF signal to produce an amplified inbound RF signal. The receiver section may then mix in-phase (I) and quadrature (Q) components of the amplified inbound RF signal with in-phase and quadrature components of a local oscillation to produce a mixed I signal and a mixed Q signal. The mixed I and Q signals are combined to produce an inbound symbol stream. In this embodiment, the inbound symbol may include phase information (e.g., $\pm\Delta\theta$ [phase shift] and/or $\theta(t)$ [phase modulation]) and/or frequency information (e.g., $\pm\Delta f$ [frequency shift] and/or $f(t)$ [frequency modulation]). In another embodiment and/or in furtherance of the preceding embodiment, the inbound RF signal includes amplitude information (e.g., $\pm\Delta A$ [amplitude shift] and/or $A(t)$ [amplitude modulation]). To recover the amplitude information, the receiver section includes an amplitude detector such as an envelope detector, a low pass filter, etc.

The baseband processing converts the inbound symbol stream into inbound data (e.g. control channel data) in accordance with one or more wireless communication standards (e.g., GSM, CDMA, WCDMA, HSPA, HSDPA, WiMAX, EDGE, GPRS, IEEE 802.11, Bluetooth, ZigBee, universal mobile telecommunications system (UMTS), long term evolution (LTE), IEEE 802.16, evolution data optimized (EV-

DO), proprietary protocol, etc.). Such a conversion may include one or more of: digital intermediate frequency to baseband conversion, time to frequency domain conversion, space-time-block decoding, space-frequency-block decoding, demodulation, frequency spread decoding, frequency hopping decoding, beamforming decoding, constellation demapping, deinterleaving, decoding, depuncturing, and/or descrambling.

The WP TX unit 10 communicates with the devices 12-14 via the control channel to facilitate efficient wireless power transfer from the WP TX unit 10 to the power RX circuit 22, 28 of the devices 12-14. For example, the communication may be to determine which frequency to use, to reposition the device 12-14 to improve magnetic coupling, to tune the components of the power TX circuit 16 and/or the power RX circuit 22, 28, to indicate desired power levels, to adjust power levels, etc. As such, during the wireless transfer of energy from the power TX circuit 16 to the power RX circuit 22, 28 of one or more devices 12-14, the WP TX unit 10 and the devices 12-14 communicate to provide a desired performance level of wireless energy transfer.

In another example of operation, the receive unit processing module 26, 32 functions to identify the control channel protocol used by the wireless power transmit unit 10 for control channel communications. Note that the control channel includes one of a plurality of control channel protocols that includes at least one or more standard control channel protocols and/or one or more proprietary control channel protocols. Further note that the transmit unit transceiver 20 uses one of the control channel protocols and is capable of using a subset of the plurality of control channel protocols. For instance, one transmit unit transceiver 20 may use a Bluetooth protocol or a proprietary protocol for its control channel protocol, while another transmit unit transceiver 20 of another wireless power transmit unit 10 may use a different control channel protocol. As such, the receive unit needs to identify the control channel protocol.

The receive unit processing module 26, 32 may identify the control channel protocol by interpreting a beacon signal transmitted by the transmit unit transceiver to determine the control channel protocol. Alternatively, or in addition to the preceding example, the receive unit processing module 26, 32 may identify the control channel protocol by receiving a set-up communication from the transmit unit transceiver 20 using a default control channel protocol. As another alternative, or in addition to one or more of the preceding examples, the receive unit processing module 26, 32 may identify the control channel protocol by scanning a frequency spectrum for control channel activity to produce scanned frequency spectrum and identify the control channel protocol from the scanned frequency spectrum. As yet another alternative, or in addition to one or more of the preceding examples, the receive unit processing module 26, 32 may identify the control channel protocol by evoking a trial and error system using known control channel protocols.

When the receive unit processing module 26, 32 identifies the control channel protocol, it determines whether the receive unit transceiver is capable of communication using the control channel protocol. For example, the processing module is determining whether the receive unit transceiver 24, 30 can be configured to support the control channel protocol. When the receive unit transceiver 24, 30 is capable of communication using the control channel protocol, the processing module coordinates configuration of the receive unit transceiver to transceive the communication regarding the wireless power magnetic field via the control channel. Con-

figuring of the receive unit transceiver **24, 30** is discussed in greater detail with reference to FIG. 6.

As yet another alternative to identifying the control channel protocol, the transmit unit transceiver **20** and the receive unit transceiver **24, 30** may negotiate which control channel protocol to use. For example, the transmit unit transceiver may transceive negotiation information (e.g., what protocols they each support, desired data rate, available bandwidth, etc.) with the receive unit transceiver to mutually select the control channel protocol.

If the processing module **26, 32** cannot identify the control channel or the receive unit transceiver **24, 30** is not capable of being configured to use the control channel protocol, the processing module determines whether the receive unit transceiver is lacking hardware or lacking software to support the control channel protocol. When the receive unit transceiver is lacking software, the processing module generates a network message to download the software to support the control channel protocol. Once the software is downloaded, the receive unit transceiver **24, 30** is configured to support the control channel protocol.

With the control channel established between the wireless power transmit unit **10** and the device **12, 14**, the wireless power transmit circuit **16** generates a wireless power magnetic field in accordance with the control channel data (e.g., power level, frequency, tuning, etc.). The wireless power receive circuit **22, 28** converts the wireless power magnetic field into a voltage, which may be used to charge a battery of the device and/or to power at least a portion of the device **12, 14**.

FIG. 2 is a schematic block diagram of another embodiment of a wireless power system that includes a wireless power (WP) transmit (TX) unit **10** and one or more devices. The WP TX unit **10** includes a processing module **18**, a WP transceiver **20**, an RFID (radio frequency identification) tag and/or reader **48**, and a power TX circuit **16**. Each device **12-14** includes a WP receive (RX) circuit **24, 28**, a processing module **26, 32**, an RFID tag and/or reader **50, 52**, and a WP transceiver **24, 30**. The device **12-14** will most likely include a plurality of other components depending on its desired functionality. For example, the device may be a cell phone, a personal audio/video player, a video game unit, a toy, etc. and it includes the corresponding circuitry.

In this embodiment, the RFID tags **48, 50, 52** include information regarding the wireless power requirements and capabilities of the devices **12-14** and of the WP TX unit **10**. For instance, the information may include the communication protocol to use (e.g., one or more of the standardized protocols **40, 44** or one or more of the proprietary protocols **42, 46**), the wireless power frequency spectrum, impedance matching information, battery charging requirements, etc. The RFID readers and tags **48, 50, 52** may be active or passive devices and may use backscattering to communicate. As such, the devices **12-14** initially communicate with the WP TX unit **10** to exchange set up information and, once set up, the devices **12-14** communicate with the WP TX unit **10** via the WP transceivers **20, 24, 30**.

FIG. 3 is a schematic block diagram of another embodiment of a wireless power system that includes a wireless power (WP) transmit (TX) unit **10** and one or more devices **12-14**. The WP TX unit **10** includes a processing module **18**, an RFID (radio frequency identification) tag and/or reader **48**, and a power TX circuit **16**. Each device **12-14** includes a WP receive (RX) circuit **22, 28**, a processing module **26, 32**, and an RFID tag and/or reader **50, 52**. The device **12-14** will most likely include a plurality of other components depending on its desired functionality. For example, the device may be a cell

phone, a personal audio/video player, a video game unit, a toy, etc. and it includes the corresponding circuitry.

In this embodiment, the RFID tags **48, 50, 52** include information regarding the wireless power requirements and capabilities of the devices **12-14** and of the WP TX unit **10**. For instance, the information may include the communication protocol to use (e.g., one or more of the standardized protocols **54** or one or more of the proprietary protocols **56**), the wireless power frequency spectrum, impedance matching information, battery charging requirements, etc. In addition to exchanging set up information, the WP TX unit **10** and the devices **12-14** use the RFID tags and readers **48, 50, 52** as the primary communication means between them. Note that the RFID readers and tags **48, 50, 52** may be active or passive devices and may use backscattering to communicate.

FIG. 4 is a schematic block diagram of another embodiment of a wireless power system that includes the WP TX unit **10** and a device **58**. The device **58** includes the power receiver circuit **62**, a battery charger **64**, a battery **66**, a DC-to-DC converter **68**, the processing module **70**, memory **72**, a plurality of input/output (I/O) modules **74**, a plurality of circuit modules **76-78**, a clock generation unit **80**, and a power management unit **82**. Note that the device **58** may be one of the devices **12-14** of FIGS. 1-3.

In an example of operation, after the WP TX unit **10** and the device **58** have established communication, the WP TX unit **10** generates a magnetic field that is received by the power receiver circuit **62**, which is integrated into device **58**. This will be discussed in greater detail with reference to one or more of the subsequent figures. The power receiver circuit **62** generates an AC voltage from the magnetic field, rectifies the AC voltage to produce a rectified voltage, and filters to the rectified voltage to produce a DC voltage rail (e.g., V+ and V-). The power receiver circuit **62** may be tuned based on control signals provided by the processing module **70**. The tuning includes adjusting one or more electromagnetic properties, such as the quality factor of the circuit, adjusting impedance, current limiting, etc., of the magnetic field and/or the wireless power receiver circuit **62**.

The battery charger **64** converts the DC voltage rail into a battery charge voltage, which it provides to the battery **66**. The battery charger **64** monitors the charging to insure proper charging in accordance with the type of battery and, once the battery **66** is charged, may implement a trickle charge. Note that the processing module **70** may provide control signals to the battery charger **64** to regulate the charging in accordance with the type of battery.

The DC-to-DC converter **68** converts the battery voltage (e.g., 1.5 volts, 4.2 volts, etc.) into one or more supply voltages (e.g., 1 volt, 2.2 volts, 3.3 volts, 5 volts, 12 volts, etc.). The DC-to-DC converter **68** provides the supply voltages to one or more of the other modules **70, 72, 74, 76, 78, 80** under the direction of the power management module **82**. In general, the power management module **82** functions to control power consumption by the device **58** to an optimal level (e.g., balancing of performance and battery life). In this regard, the power management module **82** may treat each module **70, 72, 74, 76, 78, 80** as a separate power island that can be individually controlled. For example, when a circuit module **76-78** is inactive, the power management module **82** may remove power from the circuit module **76-78**. As another example, the power management module **82** may reduce the voltage provided to a circuit module **76-78** when the circuit module **76-78** does not need to operate at its maximum potential.

In addition to controlling the supply voltage to each power island, the power management module **82** may control the clock signals provided to each circuit module **76-78** that uses

a clock signal. For example, when a circuit is idle, the power management module **82** may provide a reduced supply voltage to the circuit module **76-78**, but disable the clock signal provided to the circuit module **76-78**. In this way, minimal power is consumed, but the circuit module **76-78** may be quickly activated when it is needed. As another example, the power management module **82** may reduce the frequency of a clock signal for a circuit module **76-78** when the circuit module **76-78** does not need to operate at its maximum potential.

The plurality of circuit modules **76-78** provides at least some of the functionality for the device **58**. For example, if the device is a cell phone, the circuit modules **76-78** may provide a digital image capture function, a digital image display function, an audio file playback function, a data messaging function, a voice call function, etc. The plurality of input/output (I/O) modules **74** provides the interface to the user input/output components (e.g., speaker, microphone, display, buttons, etc.) of the device **58**. For example, a circuit module may generate outbound data (e.g., a captured digital image). The processing module processes the outbound data to produce processed data (e.g., generates a digital image file) and provides the processed outbound data to an input/output module for display on a peripheral output component (e.g., an LCD display). As another example, an input/output module may receive inbound data (e.g., a place call command) from a peripheral input component (e.g., keypad of the device) and provide it to the processing module. The processing module processes the inbound data to produce processed inbound data (e.g., retrieve the phone number of the target identified in the call command). The processing module provides the processed inbound data to a circuit module, which performs a function on the processed inbound data (e.g., places the call to the target).

FIG. **5** is a schematic block diagram of an embodiment of a portion of a wireless power system that includes the power transmitter circuit **84** and the power receiver circuit **86**. The power transmitter circuit **84** includes a coil (i.e., an inductor), a rectify and regulate circuit **88**, an impedance matching and excitation circuit **90**, a processing module **92**, and an RF and/or MMW transceiver **94**. The power receiver circuit **86** includes a coil, an impedance matching and rectify circuit **96**, a regulate circuit **98**, and an RF and/or MMW transceiver **100**. The power receiver circuit **86** is coupled to the battery charger **104** and the processing module **102**. In this regard, the power receiver circuit **84** is readily integrated into the device and uses components of the device (e.g., the processing module **102**). As such, the power receiver circuit **86** is not a standalone component coupled to the device, but an integral part of the device. Note that the device **12**, **14**, **58** will typically include a housing, which houses the power receiver circuit **86**, the battery charger **104**, the battery **106**, and the RF/MMW transceiver **100**, the processing module **102**, and the components as shown in FIG. **4**.

In an example of operation, the rectify and regulate circuit of the power transceiver circuit **84** converts an AC voltage (e.g., 110 VAC, 220 VAC, etc.) into a DC voltage (e.g., 160 VDC, 320 VDC, etc.). The impedance matching and excitation circuit **90** couple the TX power coil to the DC voltage in an alternating pattern (e.g., a full bridge inverter, a half bridge inverter) at a given frequency (e.g., 10 MHz, etc.). The impedance matching allows the LC circuit of the capacitor and coil to be tuned to a desired resonant frequency and to have a desired quality factor. For example, the LC circuit may be tuned to resonant at the excitation rate.

The coil of the power RX **86** unit is proximal to the coil of the TX unit **84** to receive the magnetic field created by the TX

coil and to create an AC voltage therefrom. The LC circuit of the RX coil and capacitor may be tuned to have a desired resonance and/or a desired quality factor. The impedance matching and rectify circuit **96** rectifies the AC voltage of the RX coil to produce a DC rail voltage that is regulated via the regulation circuit. The remainder of the diagram functions as previously discussed and/or as will be subsequently discussed.

FIG. **6** is a schematic block diagram of an embodiment of a wirelessly powered device **108** that includes the power RX circuit **110**, an RF and/or MMW data processing module **112** (which may be implemented within the processing module) and the RF and/or MMW transceiver **114**. The RF and/or MMW data processing module **112** includes an outbound symbol conversion module **116**, a baseband control module **118**, a transceiver control module **120**, and an inbound symbol conversion module **122**. The RF and/or MMW transceiver **114** includes a transmitter **124** and a receiver **126**. The transmitter **124** includes a low IF (e.g., 0 to a few MHz) bandpass filter **128**, a mixing module **130**, a power amplifier (PA) **132**, and an RF bandpass filter **134**. The receiver **126** includes an RF bandpass filter **136**, a low noise amplifier (LNA) **138**, a mixing module **140**, and a low IF bandpass filter **142**. If the transmitter **124** and receiver **126** share an antenna, the transceiver **114** further includes a TX/RX isolation circuit **144** (e.g., a circulator, a transformer balun, a TX/RX switch, etc.).

In an example of operation, the data processing module **112** configures itself based on the communication protocol being implemented and the corresponding data modulation. In addition, the transceiver control module provides control signals to the transceiver **114** to adjust one or more of the components thereof based on the protocol being implemented. In this regard, the data processing module **112** and the transceiver **114** may be configured to implement one or more of the standard communication protocols and/or one or more of the proprietary communication protocols. Note that the device **108** may include one or more configurable RF/MMW data processing modules **112** and/or one or more configurable RF/MMW transceivers **114**.

FIG. **7** is a schematic block diagram of an embodiment of a portion of a wireless power system that includes the power transmitter circuit **144** and the power receiver circuit **146**. The power transmitter circuit **144** includes a rectify and regulate circuit **148**, an impedance matching and excitation circuit **150**, a processing module **152**, an NFC modulator/demodulator **154**, and an NFC coil **156**. The power receiver circuit **146** includes an impedance matching and rectify circuit **158**, a regulate circuit **160**, an NFC modulator/demodulator **162**, and an NFC coil **164**. The power receiver circuit **146** is coupled to the battery charger (not shown in figure) and the processing module **166**.

In an example of operation, the rectify and regulate circuit **148** of the power transmitter circuit **144** converts an AC voltage (e.g., 110 VAC, 220 VAC, etc.) into a DC voltage (e.g., 160 VDC, 320 VDC, etc.). The impedance matching and excitation circuit **150** couple the TX power coil to the DC voltage in an alternating pattern (e.g., a full bridge inverter, a half bridge inverter) at a given frequency (e.g., 10 MHz, etc.). The impedance matching allows the LC circuit of the capacitor and coil to be tuned to a desired resonant frequency and to have a desired quality factor. For example, the LC circuit may be tuned to resonant at the excitation rate.

The coil of the power receiver circuit **146** is proximal to the coil of the transmitter circuit **144** to receive the magnetic field created by the TX coil and to create an AC voltage therefrom. The LC circuit of the RX coil and capacitor may be tuned to have a desired resonance and/or a desired quality factor. The

11

impedance matching and rectify circuit 158 rectifies the AC voltage of the RX coil to produce a DC rail voltage that is regulated via the regulation circuit 160.

The device communicates to the power transmitter circuit 144 via NFC (near field communication) 170. For example, when the device has data to convey to the power transmitter circuit 144, the processing module 166 generates the data, which it provides to the NFC modulator/demodulator 162. The NFC mod/demodulator 162 modulates the data at a given frequency (e.g., 13 MHz, 900 MHz, etc.) that drives the NFC coil 164. The NFC coil 164 creates a magnetic field that is received by the NFC coil 156 of the power transmitter circuit 144. The NFC mod/demod unit 154 demodulates the signal produced by the NFC coil 156 to recover the transmitted data, which is provided to the processing module 152. Data from the power transmitter circuit 144 to the device is processed in a similar manner.

FIG. 8 is a schematic block diagram of another embodiment of a portion of a wireless power system that includes the power transmitter circuit 172 and the power receiver circuit 174. The power transmitter circuit 172 includes a rectify and regulate circuit 176, an impedance matching and excitation circuit 178, a processing module 190, an NFC modulator/demodulator 188, 200, and a share WP & NFC coil 202. The power receiver circuit 174 includes an impedance matching and rectify circuit 204, a regulate circuit 206, an NFC modulator/demodulator 216, 220, and an NFC coil 222. The power receiver circuit 174 is coupled to the battery charger (not shown in figure) and the processing module 218.

In an example of operation, the rectify and regulate circuit 176 of the power transmitter circuit 172 converts an AC voltage (e.g., 110VAC, 220VAC, etc.) into a DC voltage (e.g., 160 VDC, 320 VDC, etc.). The impedance matching and excitation circuit 178 couple the TX power coil 202 to the DC voltage in an alternating pattern (e.g., a full bridge inverter, a half bridge inverter) at a given frequency (e.g., 10 MHz, etc.). The impedance matching allows the LC circuit of the capacitor and coil to be tuned to a desired resonant frequency and to have a desired quality factor. For example, the LC circuit may be tuned to resonant at the excitation rate.

The coil 202 of the power receiver circuit 174 is proximal to the coil 222 of the power transmitter circuit 172 to receive the magnetic field created by the TX coil 202 and to create an AC voltage therefrom. The LC circuit of the RX coil 222 and capacitor may be tuned to have a desired resonance and/or a desired quality factor. The impedance matching and rectify circuit 204 rectifies the AC voltage of the RX coil 222 to produce a DC rail voltage that is regulated via the regulation circuit.

The device communicates with the WP TX unit via NFC (near field communication) using the shared WP & NFC coils 202, 222. For example, when the device has data to convey to the WP TX unit, the processing module 218 generates the data, which it provides the NFC data modulator 216. The NFC modulator 216 modulates the data at a given frequency (e.g., 13 MHz, 900 MHz, etc.) to produce an amplitude component (A(t)) 212 and a phase component ($\Phi(t)$) 214. The phase component 214 adjusts the phase of an oscillation ($\cos(\omega(t))$) to produce a phase adjusted oscillation ($\cos(\omega(t)+\Phi(t))$) 210. The power amplifier 208 amplifies the phase adjusted oscillation 210 by the amplitude component 212 to produce an amplitude modulated and phase adjusted signal ($A(t)\cos(\omega(t)+\Phi(t))$). The signal is AC coupled to the shared WP & NFC coil 222 for conveyance to the WP TX unit.

The shared coil 202 of the WP TX unit receives the signal (e.g., $A_0 \cos(\omega(t)) * A(t)\cos(\omega(t)+\Phi(t))$, where A_0 is the amplitude of the WP signal and ω_0 corresponds to the frequency of

12

the WP signal). The NFC signal component is AC coupled to the data demodulator 200 and the WP component is provided to the impedance matching circuit 178. The data demodulator 200 recovers the data from the amplitude component 186 and the phase component 184 and provides the data to the processing module 190.

FIG. 9 is a schematic block diagram of another embodiment of a wireless power system that includes the WP TX unit 226 and a device 228. The device 228 includes the WP coil 230, the power RX circuit 232, the battery charger 234, the battery 236, a multiplexer 238 or the like, the DC-to-DC converter 240, the processing module 242, the IO interface modules 244, the memory 246, the power management unit 248, an NFC power recovery module 252, and/or an RF/MMW power recovery module 250.

In an example of operation, when the battery 236 is dead or near dead and as insufficient power to power minimal circuitry to facilitate battery charging, the NFC power recovery module 252 and/or RF/MMW power recovery module 250 generate an emergency voltage to provide the energy to initiate battery charging. Once energy is being received from the WP TX unit 226, the emergency supply generators may be disabled and the supply voltage V1 may be used to power the device 228 during charging and/or after charging is complete (i.e., in a trickle charge mode). Note that as long as WP energy is being received, the device 228 may be powered by V1 or another voltage derived from the WP energy.

FIG. 10 is a schematic block diagram of another embodiment of a wirelessly powered device 254 that includes the processing module 256, the rectify and impedance matching circuit (e.g., capacitors and diodes) 258, the RX coil 260, a buck &/or boost converter 262, a trickle charge circuit 264, a battery 266, and a battery current sensor 268. The processing module 256 implements a battery charger controller 270, a boost controller 272, a buck controller 274, an impedance matching control 280, and an RF/MMW and/or NFC data processing module 276. The processing module 256 may further implement the power management unit 282. Note that the processing module 256 may be fabricated on a single integrated circuit or on a multiple integrated circuit with one or more of the components of the converter 262, the rectifier circuit 258, the trickle charge circuit 264, and/or the battery current sense 268.

In an example of operation, the RX coil 260 (which may include one or more adjustable inductors) receives a magnetic field from the WP TX unit and creates an AC voltage therefrom. The adjustable capacitor is tuned (alone in conjunction with the RX coil 260) to a desired resonance, impedance, and/or quality factor to facilitate the creation of the AC voltage. The full bridge rectifier (e.g., the diodes) rectify the AC voltage to produce a rectified voltage that is filtered by the capacitor to produce a DC rail voltage (e.g., 3-20 volts).

The buck and/or boost converter 262 is enabled in a buck converter mode when the DC voltage rail is to be stepped down to produce battery charge voltage (and the supply voltage Vdd for the device) and is enabled in boost converter mode when the DC rail voltage is to be stepped up to produce the battery charge voltage (and the supply voltage Vdd). Note that when the buck and/or boost converter 262 is in the boost mode, the buck transistor is enabled. Further note that the buck and/or boost converter 262 may include multiple inductors, transistors, diodes, and capacitors to produce multiple supply voltages.

When the battery 266 is charging, the battery charge control module 270 monitors the battery current and voltage to insure charging is in accordance with the charging requirements of the battery 266. When the battery 266 is charged, the

13

battery 266 is disconnected from the converter 262 (which may be disabled or enabled to provide Vdd) and the battery 266 may be trickle charged. Note that when the WP is lost, the battery 266 is coupled to provide the power for the device 254.

FIG. 11 is an example state diagram of a processing module of a wirelessly powered device 12-14, 58 that includes six states 286: idle 284, charge set up 288, charge 290, trickle charge 292, WP operated-power management 294, and battery operated-power management 296. The device starts in the idle state 284 and waits to detect the WP TX unit, WP operation enablement, or battery operation enablement. The device may be in one of the charge states 286 and the WP operated-power management state 294 concurrently.

When the device detects the WP TX unit (e.g., via RFID communication, via control channel communication, via sensing a magnetic field, etc.), the device transitions from the idle state 284 to the charge set up state 288. When in the charge set up state 288, the device functions as referenced in FIGS. 12 and/or 13, which will be subsequently discussed. The device transitions back to the idle state 284 if the set up failed, which may result from failing to establish a control channel communication, the WP TX unit not being able to currently service the device, circuit damage, a bad battery, or loss of connection.

The device transitions to the charge state 290 when the charge set up is complete. While in the charge state 290, the device functions as referenced in FIGS. 14 and/or 15, which will be subsequently discussed. The device transitions to the idle state 284 if the charging failed or the charging is complete and the battery does not require a trickle charge. If the charging is complete and the battery will be trickle charged, the device transitions to the trickle charge state 292. The device stays in this state until a failure occurs (e.g., loss of connection with the WP TX unit) or until the trickle charge is complete. In either event, the device transitions back to the idle state 284.

When the device is enabled for operation, the device transitions to the WP operated-power manage state 294 when the device is enabled and is connected to the WP TX unit. While in this state, the device functions as referenced in FIG. 16, which will be subsequently discussed. The device transitions back to the idle state 284 when the device is disabled (e.g., turned off, placed in a sleep mode, etc.). Note that while the device is in this state, it may also be in one of the charge states.

The device transitions from the WP operated state 294 to the battery operated-power manage state 296 when the device is disconnected from the WP TX unit. The device may also enter the battery-operated state 296 from the idle state 284 when the device is enabled and not connected to the WP TX unit. While in this state, the device functions as referenced in FIG. 17, which will be subsequently discussed. The device transitions back to the WP operated state 294 when the device is again connected to the WP TX unit. The device transitions back to the idle state 284 when the device is disabled (e.g., turned off, sleep mode, low battery, etc.).

In an embodiment, the device may include an integrated circuit (IC) that includes at least a portion of a wireless power receiver circuit 86 (e.g., an on-chip coil, an on-chip variable capacitor, components of the impedance matching & rectify circuit 96 (diodes of the rectify circuit may be off-chip), and components of the regulation circuit 98), a transceiver, and a processing module. The wireless power receiver circuit converts the electromagnetic signal into a voltage and the transceiver, when operable, transceives a control channel communication.

The processing module is operable to transition the device from an idle state to a charge state when a wireless power

14

transmitter unit is detected. The processing module is further operable to transition the device from the idle state to a wireless power operated state when a wireless power transmit circuit is detected and the device is enabled. The processing module is still further operable to transition the device from the idle state to a battery operated state when the device is enabled and the wireless power transmit circuit is not detected.

Alternatively, or in addition to the above, the processing module may be operable to detect availability of the wireless power transmitter unit via the control channel communication. The processing module may then, when the wireless power transmitter unit is available, determine battery charging needs and whether the device is active. The processing module may then, when the battery charging needs compares unfavorable to a threshold, initiate battery charging using the voltage. The processing may, when the device is active, enable wireless power operation and, when the wireless power transmitter is not available, enable battery operated mode for the device.

FIG. 12 is a logic diagram of an embodiment of a method for a charge set up state 298 that begins with the device working with the WP TX unit to select a standardized communication protocol 300. Examples of the communication protocols were presented with reference to FIGS. 1-3. Note this step may begin by assuming a default communication protocol (e.g., RFID, Bluetooth, etc.) to initiate communication and then, once communication is established, selecting another communication protocol. The method continues with the device determining whether the device is synchronized via a control channel with the WP TX unit 302. In other words, is a useable control channel established between the device and the WP TX unit? If yes, the method continues with the device establishing a control channel communication with the WP TX unit 304 and exiting the state 306.

If a control channel is not established, the method continues with the device determining whether it has exhausted its standardized communication protocols 308 (e.g., the ones it is capable of executing). If not, the process repeats with the device selecting another standardized protocol 300. If the standardized protocols are exhausted, the method continues with the device selecting a proprietary communication protocol 310. Note that the method may begin with proprietary protocols and if they are exhausted, then try standardized protocols. Further note that there may be no distinction between a standard protocol and a proprietary protocol such that the method attempts to find a useable protocol regardless of whether it is a standard or proprietary protocol.

The method continues with the device determining whether the device is synchronized via a control channel with the WP TX unit using the proprietary protocol 312. If yes, the method continues with the device establishing a control channel communication with the WP TX unit 314 using the proprietary protocol and exiting the state 318.

If a control channel is not established using a proprietary protocol, the method continues with the device determining whether it has exhausted its proprietary communication protocols 316 (e.g., the ones it is capable of executing). If not, the process repeats with the device selecting another proprietary protocol 310. If the proprietary protocols are exhausted, the method continues with the device exiting this state due to a failure 318.

FIG. 13 is a logic diagram of another embodiment of a method for a charge set up state 320 that begins with the device reading an RFID tag of the WP TX unit 322 to determine a desired control channel protocol. The method continues with the device determining whether it is capable of

15

executing the desired control channel protocol **324**. If yes, the method continues with the device establishing a control channel communication with the WP TX unit **326** and exiting the state **328**.

If the device does not have the desired control channel protocol, the method continues with the device determining whether it includes the hardware to support the desired control channel protocol **330**. For example, does it include the NFC circuitry, the RF circuitry, and/or the MMW circuitry to support the operating frequency, power requirements, transmission range, etc. of the desired control channel protocol. If yes, then the device is lacking the desired control channel protocol software and the method continues with the device downloading the software for the desired control channel protocol **332**. After the device has the software, the method continues with the device establishing a control channel communication with the WP TX unit **326**.

If the device does not have the hardware to support the desired control channel protocol, the method continues with the device determining whether it can use RFID as the control channel protocol with the WP TX unit **334**. In an embodiment, the device requests that they use RFID, if the WP TX unit agrees, then the method continues with the device using RFID for the control channel with the WP TX unit **336**. If the device cannot use RFID for the control channel, then the device exits the state due to a failure **338**.

FIG. **14** is a logic diagram of an embodiment of a method for a charge state **340** that begins with the device determining the level of its battery **342** (e.g., the battery life left based on the battery type, the power demands of the device, etc.). The method continues with the device determining if the battery needs charging **344-346**. For example, has the power capacity of the battery been drained below a threshold, which may be based on battery life, not being fully charged, and/or some other criteria.

The method branches back to the beginning if the battery does not need charging and branches to the next step if it does. At the next step, the device communicates with the WP TX unit to determine one or more of: impedance matching settings, operating frequency, power level, number of coils, etc **348**. The method continues with the device determining whether it needs to adjust one or more of the impedance of its power RX circuit, the operating frequency of the power RX circuit, the power level, etc. and making the appropriate adjustments as needed **350**.

The method continues with the device setting charging parameters **352** (e.g., Vdd, current limits, trickle level, charge time intervals, etc.). The method continues with the device charging the battery and monitoring the charging **354** (e.g., the charging current and/or the charging voltage). The device also determines whether it is still in range of the WP TX unit **356**. If so, the method continues with the device determining whether the charging is complete **358**. If not, the process continues by setting (i.e., adjusting if needed in subsequent repetitions of the loop) the charging parameters **348**. If the device is out of range, the method continues with the device exiting this state due to a failure **360**. The device also exits this state **360** if the battery is charged.

FIG. **15** is a diagram of an example of a graph of charge need versus charge efficiency that may be used by the device to determine whether charging is needed as mentioned in the logic diagram of FIG. **14**. As can be inferred by the diagram of FIG. **15**, the determination of whether charging is needed is a sliding scale that varies based on battery life and charging efficiency. As such, when the battery life is high, don't charge the battery unless it can be done efficiently. As the battery life

16

diminishes, the need to charge it is greater, which, at some point, outweighs the desired for the charging to be done efficiently.

FIG. **16** is a logic diagram of an embodiment of a method for a wirelessly powered power management state **362** that begins with the device determining whether the battery needs charging **364**. If not, the method continues with the device disconnecting the battery from the charger **366**. The device may engage a trickle charge if desired or required per the battery charging requirements. The method continues with the device determining the activation status of the circuit modules **368** (e.g., disabled, active, idle, etc.). The method continues with the device determining clock signals for the active circuit modules **370** (e.g., select clock rate to just meet operational needs, which will typically be less than a maximum clock rate).

The method continues with the device determining supply voltages for the active and idle circuit modules **372**. For example, the device may set the power levels for idle circuit modules at a level to provide just enough energy to determine whether the circuit module is to remain in the idle state or transition into an active state. As another example, the device may set the power level for active circuits modules to a level just sufficient enough for the circuit module to perform its task, which will typically be less than a maximum power level.

The method continues with the device enabling the clock signals for the active circuits and providing the selected power levels to the active and idle circuit modules **374**. The method continues with the device determining whether it is still connected to the WP TX unit **376**. If yes, the method repeats from the beginning. If not, the method continues with the device exiting the state **378**. Note that in this state, power management of the device is a less critical task than when the device is battery operated. As such, the setting of the clock signal rates and power levels may be set near maximum values to enhance performance.

FIG. **17** is a logic diagram of an embodiment of a method for a battery powered power management state **380** that begins with the device disconnecting the battery from the charger and connecting it as the primary power source **382**. The method continues with the device determining activation status of the circuit modules **384** (e.g., disabled, active, idle, etc.). The method continues with the device determining, for each active circuit module, a minimum acceptable clock signal and a minimum acceptable supply voltage **386** (e.g., Vdd).

The method continues with the device enabling generation of the minimum acceptable clock signals by the clock generator and the minimum acceptable supply voltages by the converter **388**. The method continues with the device determining, for each idle circuit module, a minimum acceptable idle supply voltage and no clock signal **390**. The method continues with the device enabling generation of the idle supply voltage by the converter **392**. The method continues with the device determining whether it is still in the battery mode **394**. If yes, the method repeats. If not, the device exits this state **396**.

FIG. **18** is a schematic block diagram of an embodiment of a wireless power computer system that includes a computer **600**, a wireless keyboard **602**, a wireless mouse **604**, a cell phone **606**, a personal audio/video (A/V) player **608**, an external hard drive **610**, and potentially other peripheral computer devices (e.g., joy stick, touch pad, track ball, speakers, etc.). The computer **600** may be a laptop, a panel display computer (e.g., a tablet), a conventional computer, etc. and includes a wireless power module.

17

In this embodiment, the computer 600 is powered wirelessly via the power transmitter circuit 612 (i.e., a WP TX unit) and provides wireless power to the peripheral components (e.g., keyboard 602, mouse 604, cell phone 606, personal AV player 608, hard drive 610, etc.). The peripheral devices 602-610 may be wirelessly powered concurrently from the computer 600 and/or sequentially. Each of the peripheral devices 602-610 wirelessly communicates with the computer 600 using conventional wireless communication protocols (e.g., Bluetooth) and/or uses the WP control channel.

While FIG. 18 illustrates a computer system, the concepts apply to a more generic system. For example, a wireless power system may include a primary device (e.g., computer, television, monitor, cable set-top box, satellite set-top box, home electronic appliance, etc.) and at least one peripheral device (e.g., the peripheral devices of FIG. 35, audio and/or video entertainment components, remote controllers, etc.). The primary device includes a power conversion unit, a functional module, and a transceiver. The peripheral device includes a wireless power receiver, a peripheral unit, and a transceiver.

Within the primary device, the power conversion unit converts a power source into an electromagnetic signal. For example, the power conversion unit may include a power supply and a wireless power transmitter circuit. The power supply converts the power source (e.g., an AC voltage) into an output DC voltage. The wireless power transmitter circuit converts the output DC voltage into the electromagnetic signal. As another example, the power conversion unit includes a wireless power receiver circuit and a power conversion transmit circuit. The wireless power receiver circuit converts the power source (e.g., an input electromagnetic signal) into a supply voltage. The power conversion transmit circuit converts the supply voltage into the electromagnetic signal. In the latter example, the input electromagnetic signal may have a first frequency and the electromagnetic signal may have a second frequency to minimize interference therebetween.

The functional module of the primary device executes a function regarding peripheral information (e.g., communication protocol for the conveyance of the peripheral information, input data from the peripheral device, an input command from the peripheral device, output data for the peripheral device, and/or an output command for the peripheral device). For example, if the functional module is a central processing unit and the peripheral device is a user input device (e.g., touch screen, keypad, mouse, keyboard, etc.), the user input device may generate data and/or a command for execution by the central processing unit. As another example, if the functional module is memory and the peripheral device is a user output device, the memory provides data to the user output device for display (e.g., audible and/or visual).

The transceiver of the primary device communicates information regarding the electromagnetic signal with the transceiver of the peripheral device. The information regarding the electromagnetic signal includes control channel protocol, frequency of the electromagnetic signal, impedance matching parameters, resonant frequency tuning parameters, and/or other electromagnetic properties discussed herein.

The transceiver of the primary device also communicates the peripheral information with the transceiver of the peripheral device. In this regard, the transceivers are used for wireless power control channel communication and for peripheral device functional (e.g., data and/or commands) communication.

In addition to including a power conversion unit, a functional module, and a transceiver, the primary device may

18

further include a battery, a battery charger, and a processing module. The battery charger utilizes the supply voltage to charge the primary battery as discussed with reference to one or more of the figures. The processing module coordinates the charging of the battery, the communicating the information regarding the electromagnetic signal, and the communicating the peripheral information.

The wireless power receiver circuit of the peripheral device converts the electromagnetic signal into a voltage as discussed with reference to one or more of the figures. The peripheral unit of the peripheral device processes the peripheral information. For example, the peripheral unit may generate input data for the primary device, wherein the peripheral information includes the input data. As another example, the peripheral unit may generate an input command for the primary device, wherein the peripheral information includes the input command. As another example, the peripheral unit may perform a function on output data from the primary device, wherein the peripheral information includes the output data. As another example, the peripheral unit may perform a function in accordance with an output command from the primary device, wherein the peripheral information includes the output command.

In addition to including a wireless power receiver, a peripheral unit, and a transceiver, the peripheral device may further include a battery, a battery charger, and a processing module. The battery charger utilizes the supply voltage to charge the peripheral battery. The processing module coordinates the charging of the battery, the communicating the information regarding the electromagnetic signal, and the communicating the peripheral information.

The primary device and/or the peripheral device may include an integrated circuit (IC) to support the above-described functions. For example, an IC may include at least a portion of the wireless power receiver circuit (e.g., one or more of the coil, capacitor, and diodes of the rectifying circuit may be off-chip), at least a portion of the battery charger (e.g., one or more of the switching transistors, the output filter capacitor, the inductor may be off-chip), the transceiver, and the processing module.

FIG. 19 is a schematic block diagram of an embodiment of power modules (e.g., computer power module 616 and peripheral device power module 614) within a wireless power computer system. The computer power module 616 includes a wireless transceiver 620, a power receiver circuit 622, a battery charger 624, a battery 626, a power conversion transmit (TX) circuit 628, a processing module 630, and memory 632. The peripheral device power module 614 includes a wireless transceiver 634, a power receive circuit (RX ckt) 636, a battery charger 638, and a battery 640.

In an example of operation, the power transmit circuit 618 generates a magnetic field that is received by the power receiver circuit 622 of the computer power module 616 to facilitate a wireless power transference. The power receiver circuit 622 generates a DC rail voltage in accordance with control signals provided by the processing module 630. The battery charger 624 converts the DC rail voltage into a battery charge voltage, which is supplied to the battery 626. The power conversion TX circuit 628 generates a magnetic field that is magnetically coupled to the power RX circuit 636 of the peripheral device power module 614. The power conversion TX circuit 628 may be sourced by the DC rail voltage when the computer power module 616 is proximal to the power transmitter circuit 618 or the battery 626 when the computer power module 616 is not proximal to the power transmitter circuit 618.

The power RX circuit of the peripheral device power module **636** generates a DC rail voltage from the magnetic field of the power conversion TX circuit **628**. The battery charger **624** converts the DC rail voltage into a battery charger voltage, which is provided to the battery **626**. The computer power module **616** communicates with the peripheral device power module **614** via the wireless transceivers **620**, **634** (e.g., RF, MMW, and/or NFC) regarding wireless power matters (e.g., frequency selection, operating frequency, impedance matching settings, power levels, etc.). In addition, the wireless transceivers **620**, **634** may be used to convey data between the peripheral device and the computer. For example, if the peripheral device is the wireless keyboard, the keyboard signaling may be conveyed to the computer via the wireless transceivers. Note that with multiple peripheral devices, each including a wireless transceiver, a local area network is created, which requires a network level coordinate of communications therein.

A power module (e.g., computer power module **616** and peripheral device power module **614**) may include an integrated circuit (IC) to support its function. For example, the IC may include at least a portion of a wireless power receiver circuit (e.g., one or more of the coil, capacitor, and diodes of the rectifying circuit may be off-chip), at least a portion of a wireless power transmit circuit (e.g., one or more of the coil, capacitor, and the switching transistors of the DC-to-AC circuit may be off-chip), and the transceiver. The wireless power receiver circuit is operable to convert an electromagnetic signal into a voltage, wherein a wireless power transmitter unit generates the electromagnetic signal. The wireless power transmit circuit is operable to convert the voltage into a second electromagnetic signal. The transceiver communicates first information regarding the first electromagnetic signal, communicates second information regarding a second electromagnetic signal, and communicates peripheral information regarding execution of a function.

FIG. **20** is a schematic block diagram of an embodiment of a computer power module **642** that includes the power receiver circuit **644**, the battery charger **648**, the battery **650**, the power conversion TX circuit **646**, the wireless transceiver **652**, and the processing module **654**. The power receiver circuit **644** includes the RX coil **656**, an adjustable capacitor **658**, the impedance matching & rectify circuit **660**, the regulation circuit **662**, and the control channel transceiver **664**. The power conversion TX circuit **646** includes a multiplexer **666**, a DC-to-AC converter **668**, an impedance matching circuit **670**, an adjustable capacitor **672**, and a coil **674**.

In an example of operation, the RX coil **656** of the power receiver circuit **644** generates an AC voltage from the magnetic field it receives from the TX coil of the WP TX unit. The impedance matching and rectify circuit **660** converts the AC voltage into a DC rail voltage that is regulated via the regulation circuit **662**. The battery charger **648** uses the DC rail voltage to charge the battery **650**.

The power conversion TX circuit **646** is powered by the DC rail voltage when the computer is receiving wireless power from the WP TX unit **646** and is powered by the battery **650** when the computer is in a battery operated mode (assuming the battery **650** has sufficient energy to charge peripheral devices). When in the WP mode, the DC-to-AC converter **668** converts the DC rail voltage into an AC voltage that is provided to the coil **674** via the impedance matching circuit **670**. The coil **674** generates a magnetic field that is received by the RX coil of a peripheral device power module. In an embodiment, the AC voltage of the RX coil **656** of the power receiver circuit **644** of the computer power module **642** may have the

same or a different frequency than the AC voltage of the TX coil **674** of the power conversion TX module **646**.

When the computer is in the battery operated mode, the power conversion TX circuit **646** generates the magnetic field as described above if the battery **650** has sufficient power (e.g., a desired battery life level) to charge one or more peripheral devices. If the battery **650** does not have sufficient power, the power conversion TX circuit **646** is disabled.

FIG. **21** is a schematic block diagram of another embodiment of a computer power module **676** that includes the RX coil **678**, an adjustable capacitor **680**, rectifying diodes **682**, a storage capacitor **684**, a buck and/or boost converter **686**, the battery **688**, a battery current sense **690**, a trickle charge circuit **692**, the DC-to-AC converter **694**, another adjustable capacitor **696**, and the processing module **698**. The processing module **698** is configured to implement an RX impedance matching control module **700**, the control channel processing module **702**, a boost control module **706**, a buck control module **708**, a battery charger control module **710**, a DC-to-AC control module **712**, and a TX impedance matching control module **714**. In addition, the processing module **698** may implement the baseband processing **716** for the wireless transceiver. Note that the processing module **698** and one or more other components may be implemented on one or more integrated circuits.

In an example of operation of the back half of the circuit, the DC-to-AC module **694** receives the DC rail voltage produced by the buck and/or boost converter **686**. The DC-to-AC module **694** includes a full bridge inverter topology to excite the coil **697**. The DC-to-AC control module **712** generates the switching signals to drive the DC-to-AC module **694** at a desired frequency. The impedance matching control circuit **714** adjusts the impedance of the capacitor **696** and/or coil **697** to a desired resonance and/or quality factor. As an example, the impedance matching control circuit **714** may tune the capacitor **696** and coil **697** to resonate at the switching frequency of the DC-to-AC converter **694**, to be an under-damped circuit, or an over-damped circuit. In an alternate embodiment, the DC-to-AC converter **694** may include a half bridge inverter topology. Note that the front half of the circuit operates in a similar manner as described with reference to FIG. **10**.

FIG. **22** is a schematic block diagram of an embodiment of a peripheral device power module **722** that includes the RX coil **724**, an adjustable capacitor **726**, the impedance matching and rectifying circuit **728**, the regulation circuit **730**, the battery charger **732**, the battery **734**, the processing module **736**, and the wireless transceiver **738**.

In an example of operation, the RX coil **724** generates an AC voltage from the magnetic field it receives from the TX coil of the computer power module. The impedance matching and rectify circuit **728** converts the AC voltage into a DC rail voltage that is regulated via the regulation circuit **730**. The battery charger **732** uses the DC rail voltage to charge the battery **734**.

FIG. **23** is a schematic block diagram of another embodiment of a peripheral device power module **740** that includes the processing module **742**, the rectify and impedance matching circuit **744** (e.g., capacitors and diodes), the RX coil **746**, a buck &/or boost converter **750**, a trickle charge circuit **748**, a battery **752**, and a battery current sensor **754**. The processing module **742** implements a battery charger controller **756**, a boost controller **758**, a buck controller **760**, an impedance matching circuit **762**, and an RF/MMW and/or NFC baseband processing module **764**. Note that the processing module **742** may be fabricated on a single integrated circuit or on a multiple integrated circuit with one or more of the compo-

21

nents of the converter **750**, the rectifier circuit **744**, the trickle charge circuit **748**, and/or the battery current sense **754**.

In an example of operation, the RX coil **746** (which may include one or more adjustable inductors) receives a magnetic field from the computer power module and creates an AC voltage therefrom. The adjustable capacitor **744** is tuned (alone or in conjunction with the RX coil **746**) to a desired resonance, impedance, and/or quality factor to facilitate the creation of the AC voltage. The full bridge rectifier **744** (e.g., the diodes) rectifies the AC voltage to produce a rectified voltage that is filtered by the capacitor **744** to produce a DC rail voltage (e.g., 3-20 volts).

The buck and/or boost converter **750** is enabled in a buck converter mode when the DC voltage rail is to be stepped down to produce battery charge voltage (and the supply voltage Vdd for the device) and is enabled in boost converter mode when the DC rail voltage is to be stepped up to produce the battery charge voltage (and the supply voltage Vdd). Note that when the buck and/or boost converter **750** is in the boost mode, the buck transistor is enabled. Further note that the buck and/or boost converter **750** may include multiple inductors, transistors, diodes, and capacitors to produce multiple supply voltages.

When the battery **752** is charging, the battery charge control module **756** monitors the battery **752** current and voltage to insure charging is in accordance with the charging requirements of the battery **752**. When the battery **752** is charged, the battery **752** is disconnected from the converter **750** (which may be disable or enabled to provide Vdd) and the battery **752** may be trickle charged **748**. Note that when the WP is lost, the battery **752** is coupled to provide the power for the device.

FIG. **24** is a schematic block diagram of another embodiment of a wireless power system that includes the WP TX unit and a device **1050**. In this diagram, the power TX circuit and the RFID tag and/or reader of the WP TX unit is shown. The device **1050** includes the power RX circuit **1052**, a battery charger &/or DC-to-DC converter **1054**, a battery **1056** (which includes an RFID tag **1058**), the processing module **1060**, memory **1062**, a plurality of input/output (I/O) modules **1064**, a plurality of circuit modules **1068-1070**, a clock generation unit **1072**, an RFID tag and/or reader **1066**, and a power management unit **1074**.

In an example of operation, after the WP TX unit and the device **1050** have established communication, the WP TX unit generates a magnetic field that is received by the power RX circuit **1052** of the device **1050**. The power RX circuit **1052** generates an AC voltage from the magnetic field, rectifies the AC voltage to produce a rectified voltage, and filters to the rectified voltage to produce a DC voltage rail (e.g., V+ and V-). The power RX circuit **1052** may be tuned based on control signals provided by the processing module **1060**. The tuning includes adjusting the quality factor of the circuit, adjusting impedance, current limiting, etc.

The battery charger **1054** converts the DC voltage rail into a battery charge voltage, which it provides to the battery **1056**. The battery charger **1054** monitors the charging to insure proper charging in accordance with the type of battery and, once the battery **1056** is charged, may implement a trickle charge. Note that the processing module **1060** may provide control signals to the battery charger **1054** to regulate the charging in accordance with the type of battery **1056**.

The DC-to-DC converter **1054** converts the battery voltage (e.g., 1.5 volts, 4.2 volts, etc.) into one or more supply voltages (e.g., 1 volt, 2.2 volts, 3.3 volts, 5 volts, 12 volts, etc.). The DC-to-DC converter **1054** provides the supply voltages to one or more of the other modules under the direction of the power management module **1074**. In general, the power man-

22

agement module **1074** functions to control power consumption by the device **1050** to an optimal level (e.g., balancing of performance and battery life). In this regard, the power management module **1074** may treat each module as a separate power island that can be individually controlled. For example, when a circuit module **1068-1070** is inactive, the power management module **1050** may remove power from the circuit module **1068-1070**. As another example, the power management module **1074** may reduce the voltage provided to a circuit module **1068-1070** when the circuit module **1068-1070** does not need to operate at its maximum potential.

In addition to controlling the supply voltage to each power island, the power management module **1074** may control the clock signals provided to each circuit module **1068-1070** that uses a clock signal. For example, when a circuit **1068-1070** is idle, the power management module **1074** may provide a reduced supply voltage to the circuit module **1068-1070**, but disable the clock signal provided to the circuit module **1068-1070**. In this way, minimal power is consumed, but the circuit module **1068-1070** may be quickly activated when it is needed. As another example, the power management module **1074** may reduce the frequency of a clock signal for a circuit module **1068-1070** when the circuit module **1068-1070** does not need to operate at its maximum potential.

To facilitate charging of the battery **1056**, the RFID tag **1058** of the battery **1056** stores information regarding effective and efficient charging of the battery **1056**. For example, the information may indicate the type of battery **1056**, the number of times the battery **1056** has been charged, the desired charging current, the desired charging voltage, the desired charging duration, time base changes in the charge current, time based changes in the charging voltage, trickle charge requirements, etc. In this manner, the battery **1056** provides information regarding its optimal charging such that the device **1050** may configure itself to optimally charge the battery **1056**.

FIG. **25** is a schematic block diagram of an embodiment of a wirelessly chargeable battery **1080** that includes a coil **1090**, an impedance matching & rectify circuit **1082**, a battery charger **1084**, battery cells **1086**, and an RFID tag and/or reader **1088**. Note that the physical size of the components is dependent on the operating frequency of the charger **1084** and the charging requirements of the battery **1086**.

In an example of operation, the coil **1090** of the power RX unit is receives a magnetic field from the TX coil and creates an AC voltage therefrom. The impedance matching and rectify circuit **1082** adjusts the impedance of the coil **1090** and rectifies the AC voltage of the RX coil **1090** to produce a DC rail voltage that is regulated via the regulation circuit (not on figure). Note that impedance matching may be omitted from the in-battery battery charging circuit. The battery charger **1084** adjusts the voltage to a desired charging voltage and monitors the charging current to insure proper charging.

FIG. **26** is a schematic block diagram of another embodiment of a wirelessly chargeable battery **1092** that includes the processing module **1094**, the rectify and impedance matching circuit **1096** (e.g., capacitors and diodes), the RX coil **1098**, a buck (&/or boost) converter **1100**, a trickle charge circuit **1101**, battery cells **1102**, and a battery current sensor **1104**. The processing module **1094** implements a battery charger controller **1106**, a buck (&/or boost) controller **1108**, and an RFID data processing module **1110**. Note that the processing module **1094** may be fabricated on a single integrated circuit or multiple integrated circuit with one or more of the components of the converter **1100**, the rectifier circuit **1096**, the trickle charge circuit **1101**, and/or the battery current sense **1104**.

23

In an example of operation, the RX coil **1098** (which may include one or more adjustable inductors) receives a magnetic field from the WP TX unit and creates an AC voltage therefrom. The full bridge rectifier **1096** (e.g., the diodes) rectify the AC voltage to produce a rectified voltage that is filtered by the capacitor to produce a DC rail voltage (e.g., 3-20 volts). The buck (and/or boost) converter **1100** is enabled to step down the DC voltage rail to produce battery charge voltage (or as a boost converter to step up the DC rail voltage to produce the battery charge voltage).

When the battery **1902** is charging, the battery charge control module **1106** monitors the battery current and voltage to insure charging is in accordance with the charging requirements of the battery **1096**. When the battery **1092** is charged, the battery **1092** is disconnected from the converter **1100** (which is disabled) and the battery **1102** may be trickle charged.

FIG. **27** is a diagram of an embodiment of a wirelessly chargeable battery that includes the components shown in FIG. **25** and/or FIG. **26**. In this illustration, the RX coil is fabricated in the negative terminal and/or the positive terminal. The other components may be implemented on a flexible circuit board that conforms to the battery's shell or casing.

FIG. **28** is a diagram of another embodiment of a wirelessly chargeable battery that includes the components shown in FIG. **25** and/or FIG. **26**. In this illustration, the RX coil is fabricated in the negative terminal and the positive terminal. The other components may be implemented on a flexible circuit board that conforms to the battery's shell or casing.

As may be used herein, the terms "substantially" and "approximately" provides an industry-accepted tolerance for its corresponding term and/or relativity between items. Such an industry-accepted tolerance ranges from less than one percent to fifty percent and corresponds to, but is not limited to, component values, integrated circuit process variations, temperature variations, rise and fall times, and/or thermal noise. Such relativity between items ranges from a difference of a few percent to magnitude differences. As may also be used herein, the term(s) "operably coupled to", "coupled to", and/or "coupling" includes direct coupling between items and/or indirect coupling between items via an intervening item (e.g., an item includes, but is not limited to, a component, an element, a circuit, and/or a module) where, for indirect coupling, the intervening item does not modify the information of a signal but may adjust its current level, voltage level, and/or power level. As may further be used herein, inferred coupling (i.e., where one element is coupled to another element by inference) includes direct and indirect coupling between two items in the same manner as "coupled to". As may even further be used herein, the term "operable to" or "operably coupled to" indicates that an item includes one or more of power connections, input(s), output(s), etc., to perform, when activated, one or more its corresponding functions and may further include inferred coupling to one or more other items. As may still further be used herein, the term "associated with", includes direct and/or indirect coupling of separate items and/or one item being embedded within another item. As may be used herein, the term "compares favorably", indicates that a comparison between two or more items, signals, etc., provides a desired relationship. For example, when the desired relationship is that signal **1** has a greater magnitude than signal **2**, a favorable comparison may be achieved when the magnitude of signal **1** is greater than that of signal **2** or when the magnitude of signal **2** is less than that of signal **1**.

While the transistors in the above described figure(s) is/are shown as field effect transistors (FETs), as one of ordinary

24

skill in the art will appreciate, the transistors may be implemented using any type of transistor structure including, but not limited to, bipolar, metal oxide semiconductor field effect transistors (MOSFET), N-well transistors, P-well transistors, enhancement mode, depletion mode, and zero voltage threshold (VT) transistors.

The present invention has also been described above with the aid of method steps illustrating the performance of specified functions and relationships thereof. The boundaries and sequence of these functional building blocks and method steps have been arbitrarily defined herein for convenience of description. Alternate boundaries and sequences can be defined so long as the specified functions and relationships are appropriately performed. Any such alternate boundaries or sequences are thus within the scope and spirit of the claimed invention.

The present invention has been described above with the aid of functional building blocks illustrating the performance of certain significant functions. The boundaries of these functional building blocks have been arbitrarily defined for convenience of description. Alternate boundaries could be defined as long as the certain significant functions are appropriately performed. Similarly, flow diagram blocks may also have been arbitrarily defined herein to illustrate certain significant functionality. To the extent used, the flow diagram block boundaries and sequence could have been defined otherwise and still perform the certain significant functionality. Such alternate definitions of both functional building blocks and flow diagram blocks and sequences are thus within the scope and spirit of the claimed invention. One of average skill in the art will also recognize that the functional building blocks, and other illustrative blocks, modules and components herein, can be implemented as illustrated or by discrete components, application specific integrated circuits, processors executing appropriate software and the like or any combination thereof.

What is claimed is:

1. A device comprising:

wireless power receive circuitry to generate power from a received wireless power signal;

a first wireless power transceiver configured to communicate with a second wireless power transceiver included in a wireless power transmission unit;

a processing module coupled to the wireless power receive circuitry and the first wireless power transceiver, the processing module configured to:

transition from an idle state to a first power management state in response to the device being enabled and determining that communication has been established with the wireless power transmission unit; and

transition from an idle state to a second power management state in response to the device being enabled and determining that communication has not been established with the wireless power transmission unit.

2. The device of claim **1**, the processing module further configured to:

determine an activation status of circuit modules.

3. The device of claim **2**, the processing module is further configured to:

determine first clock signal rates and first supply voltages for active circuit modules in the first power management state;

determine second clock signal rates and second supply voltages for the active circuit modules in the second power management state; and

wherein a first clock signal rate and a first supply voltage for at least one active circuit module are closer to maxi-

25

mum values than a second clock signal rate and a second supply voltage for the same active circuit.
 4. The device of claim 2, the processing module is further configured to:
 determine that no clock signal is required by at least one idle circuit module during the second power management state.
 5. The device of claim 1, the processing module is further configured to:
 transition between the first power management state and the second power management state based on changes in a communication status with the wireless power transmission unit.
 6. The device of claim 1, further comprising:
 a battery charger coupled to the wireless power receive circuitry; and
 wherein during the first power management state the processing module is configured to determine whether a battery coupled to the wireless power receive circuitry requires charging.
 7. The device of claim 6, wherein determining whether the battery requires charging is based on a sliding scale that varies based on battery life and charging efficiency.
 8. The device of claim 6, wherein the processing module is further configured to:
 set charging parameters based on information received from the wireless power transmission unit.
 9. A wireless charging system including a wireless power (WP) receiving unit, the WP receiving unit comprising:
 a first wireless power transceiver to receive and transmit data related to wireless power transmission parameters; wireless power receive circuitry to generate power from a received wireless power signal;
 a battery coupled to the wireless power receive circuitry; and
 a processing module coupled to the wireless power receive circuitry and the first wireless power transceiver, the processing module configured to:
 transition to a WP operated power management state in response to a device associated with the wireless charging system being enabled and determining that communication has been established with the wireless power transmission unit; and
 transition to a battery operated power management state in response to the device being enabled and determining that communication has not been established with the wireless power transmission unit.
 10. The wireless charging system of claim 9, the processing module further configured to:
 determine an activation status of circuit modules coupled to the wireless charging system.
 11. The wireless charging system of claim 10, the processing module is further configured to:
 determine different clock signal rates and supply voltages for a particular active circuit module based on whether the wireless charging system is operating in the WP operated power management state or the battery operated power management state.
 12. The wireless charging system of claim 10, the processing module is further configured to:
 determine that no clock signal is required by at least one idle circuit module during the battery operated power management state.

26

13. The wireless charging system of claim 9, the processing module further configured to:
 transition between the WP operated power management state and the battery operated power management state based on changes in a communication status with the wireless power transmission unit.
 14. The wireless charging system of claim 9, further comprising:
 a battery charger coupled to the wireless power receive circuitry; and
 wherein during the WP operated power management state the processing module is configured to determine whether the battery coupled requires charging.
 15. The wireless charging system of claim 14, wherein determining whether the battery requires charging is based on a sliding scale that varies based on battery life and charging efficiency.
 16. The wireless charging system of claim 14, wherein the processing module is further configured to:
 set charging parameters based on information associated with the wireless power signal.
 17. A wireless charging device comprising:
 a RFID circuit;
 a first wireless power transceiver to receive and transmit data related to wireless transmission parameters over a RFID channel;
 wireless power receive circuitry to generate power from a received wireless power signal;
 a processing module coupled to the wireless power receive circuitry and the first wireless power transceiver, the processing module configured to:
 transition to a first power management state in response to the wireless charging device being enabled and determining that communication has been established with a wireless power transmission unit; and
 transition to a second power management state in response to the device being enabled and determining that communication has not been established with the wireless power transmission unit.
 18. The wireless charging device of claim 17, the processing module further configured to:
 determine different clock signal rates and supply voltages for active circuit modules when the wireless charging system is operating in different power management states.
 19. The wireless charging device of claim 18, the processing module further configured to:
 determine an activation status of circuit modules coupled to the wireless charging system; and
 determine that no clock signal is required by at least one idle circuit module during the second power management state.
 20. The wireless charging device of claim 18, the processing module further configured to:
 transition between the first power management state and the second power management state based on changes in a communication status with the wireless power transmission unit.
